

## Methodology

### October 2017 Political Survey

Prepared by SSRS for the Pew Research Center

October 2017

## SUMMARY

The October 2017 Political Survey, sponsored by the Pew Research Center, obtained telephone interviews with a nationally representative sample of 1,504 adults, age 18 or older, living in the United States. Interviews were conducted via landline ( $n_{LL}=378$ ) and cell phone ( $n_C=1,126$ ; including 698 without a landline phone). The survey was conducted by SSRS of Glenn Mills, PA. The interviews were administered in English and Spanish by SSRS from October 26-October 30, 2017. Statistical results are weighted to correct known demographic discrepancies. The margin of sampling error for the complete set of weighted data is  $\pm 3.0$  percentage points.

Details on the design, execution and analysis of the survey are discussed below.

## DESIGN AND DATA COLLECTION PROCEDURES

### Sample Design

Phone numbers used for this study were randomly generated from landline and cell phone sampling frames, with an overlapping frame design. The RDD landline sample was generated through Marketing Systems Group's (MSG) GENESYS sampling system. The standard GENESYS RDD methodology produces a strict single stage, Equal Probability Selection Method (EPSEM) sample of residential telephone numbers drawn from working banks with one or more residential directory listings. In other words, a GENESYS RDD sample ensures an equal and known probability of selection for every residential telephone number in the sample frame. The sample was generated shortly before the beginning of data collection to provide the most up-to-date sample possible, maximizing the number of valid telephone extensions. Following generation, the RDD sample was prepared using MSG's proprietary GENESYS IDplus procedure, which identifies and eliminates a large percentage of all non-working and business numbers. Numbers flagged as cellular, were removed from the landline sample frame prior to dialing.

## Contact Procedures

Interviews were conducted from October 25 to 30, 2017. As many as 7 attempts were made to contact every sampled telephone number. Sample was released for interviewing in replicates, which are representative subsamples of the larger sample. Using replicates to control the release of sample ensures that complete call procedures are followed for the entire sample. Calls were staggered over times of day and days of the week to maximize the chance of making contact with potential respondents. Interviewing was spread as evenly as possible across the days in field. When necessary, each telephone number was called at least one time during the day in an attempt to complete an interview.

For the landline sample, interviewers asked to speak with the youngest male or female currently at home based on a random rotation. If no male/female was available, interviewers asked to speak with the youngest adult of the other gender. This systematic respondent selection technique has been shown to produce samples that closely mirror the population in terms of age and gender when combined with cell interviewing. Prior to dialing, the landline sample was scrubbed of numbers that have been ported to wireless service by comparing the sample file to the most recently available Intermodal Ported Telephone Number Identification Service database.

For the cellular sample, interviews were conducted with the person who answered the phone. Interviewers verified that the person was an adult and in a safe place before administering the survey. Cellular respondents were offered a post-paid cash reimbursement for their participation.

## WEIGHTING AND ANALYSIS

Weighting is generally used in survey analysis to compensate for sample designs and patterns of non-response that might bias results. The sample was weighted to match national adult general population parameters. A two-stage weighting procedure was used to weight this dual-frame sample.

The first stage of weighting corrected for different probabilities of selection associated with the number of adults in each household and each respondent's telephone usage patterns.<sup>1</sup> This weighting also adjusts for the overlapping landline and cell sample frames and the relative sizes of each frame and each sample.

The first-stage weight for the  $i^{\text{th}}$  case can be expressed as:

$$WT_i = \left[ \left( \frac{S_{LL}}{F_{LL}} \times \frac{1}{AD_i} \times LL_i \right) + \left( \frac{S_{CP}}{F_{CP}} \times CP_i \right) - \left( \frac{S_{LL}}{F_{LL}} \times \frac{1}{AD_i} \times LL_i \times \frac{S_{CP}}{F_{CP}} \times CP_i \right) \right]^{-1}$$

<sup>1</sup> i.e., whether respondents have only a landline telephone, only a cell phone, or both kinds of telephone.

Where  $S_{LL}$  = the size of the landline sample  
 $F_{LL}$  = the size of the landline sample frame  
 $S_{CP}$  = the size of the cell sample  
 $F_{CP}$  = the size of the cell sample frame  
 $AD_i$  = Number of adults in household  $i$   
 $LL_i=1$  if respondent has a landline phone, otherwise  $LL=0$ .  
 $CP_i=1$  if respondent has a cell phone, otherwise  $CP=0$ .

The second stage of weighting balances sample demographics to population parameters. The sample is balanced by form to match national population parameters for sex, age, education, race, Hispanic origin, region (U.S. Census definitions), population density, and telephone usage. The Hispanic origin was split out based on nativity; U.S. born and non-U.S. born. The White, non-Hispanic subgroup was also balanced on age, education and region.

The basic weighting parameters came from the U.S. Census Bureau's 2015 American Community Survey (ACS) data.<sup>2</sup> The population density parameter was derived from Census 2010 data. The telephone usage parameter came from an analysis of the July-December 2016 National Health Interview Survey.<sup>3</sup>

Weighting was accomplished using Sample Balancing, a special iterative sample weighting program that simultaneously balances the distributions of all variables using a statistical technique called the *Deming Algorithm*. Weights were trimmed to prevent individual interviews from having too much influence on the final results. The use of these weights in statistical analysis ensures that the demographic characteristics of the sample closely approximate the demographic characteristics of the national population. Table 1 compares weighted and unweighted sample distributions to population parameters.

<sup>2</sup> ACS analysis was based on all adults excluding those living in institutional group quarters.

**Table 1: Sample Demographics**

	<u>Parameter</u>	<u>Unweighted</u>	<u>Weighted</u>
<u>Gender</u>			
	Male	48.3%	49.8%
	Female	51.7%	50.2%
<u>Age</u>			
	18-24	12.7%	12.6%
	25-34	17.6%	17.9%
	35-44	16.6%	16.3%
	45-54	17.5%	17.3%
	55-64	16.6%	16.9%
	65+	19.0%	19.1%
<u>Education</u>			
	HS Graduate or Less	40.3%	38.0%
	Some College/Assoc Degree	31.3%	32.1%
	College Graduate	28.4%	29.9%
<u>Race/Ethnicity</u>			
	White/not Hispanic	64.6%	65.5%
	Black/not Hispanic	11.7%	11.3%
	Hisp - US born	8.0%	8.0%
	Hisp - born outside	7.5%	6.9%
	Other/not Hispanic	8.2%	8.2%
<u>Region</u>			
	Northeast	17.9%	18.1%
	Midwest	21.1%	21.5%
	South	37.4%	36.2%
	West	23.6%	24.2%
<u>County Pop. Density</u>			
	1 - Lowest	19.9%	20.1%
	2	20.0%	19.9%
	3	20.1%	19.9%
	4	20.0%	20.4%
	5 - Highest	20.0%	19.7%
<u>Household Phone Use</u>			
	LLO	5.3%	4.0%
	Dual	41.2%	42.3%
	CPO	53.5%	53.7%

## Effects of Sample Design on Statistical Inference

Post-data collection statistical adjustments require analysis procedures that reflect departures from simple random sampling. SSRS calculates the effects of these design features so that an appropriate adjustment can be incorporated into tests of statistical significance when using these data. The so-called "design effect" or *deff* represents the loss in statistical efficiency that results from systematic non-response. The total sample design effect for this survey is 1.39.

SSRS calculates the composite design effect for a sample of size  $n$ , with each case having a weight,  $w_i$  as:

$$deff = \frac{n \sum_{i=1}^n w_i^2}{\left( \sum_{i=1}^n w_i \right)^2} \quad \text{formula 1}$$

In a wide range of situations, the adjusted *standard error* of a statistic should be calculated by multiplying the usual formula by the square root of the design effect ( $\sqrt{deff}$ ). Thus, the formula for computing the 95% confidence interval around a percentage is:

$$\hat{p} \pm \left( \sqrt{deff} \times 1.96 \sqrt{\frac{\hat{p}(1-\hat{p})}{n}} \right) \quad \text{formula 2}$$

where  $\hat{p}$  is the sample estimate and  $n$  is the unweighted number of sample cases in the group being considered.

The survey's *margin of error* is the largest 95% confidence interval for any estimated proportion based on the total sample—the one around 50%. For example, the margin of error for the entire sample is  $\pm 3.0$  percentage points. This means that in 95 out every 100 samples drawn using the same methodology, estimated proportions based on the entire sample will be no more than  $\pm 3.0$  percentage points away from their true values in the population. The margin of error for estimates based on each form is  $\pm 4.2$  percentage points. It is important to remember that sampling fluctuations are only one possible source of error in a survey estimate. Other sources, such as respondent selection bias, questionnaire wording and reporting inaccuracy, may contribute additional error of greater or lesser magnitude.

**RESPONSE RATE**

Table 2 reports the disposition of all sampled telephone numbers ever dialed from the original telephone number samples. The response rate estimates the fraction of all eligible sample that was ultimately interviewed. Response rates are computed according to American Association for Public Opinion Research standards.<sup>4</sup> Thus the response rate for the landline samples was 7.9 percent. The response rate for the cellular samples was 8.1 percent.
